Fuente Párrafo Editar

Think of a share of stock as a piece of a company, albeit typically a very small piece. The value of a share is loosely related to the value of the company divide by the number of outstanding shares (i.e., total shares owned by shareholders.) For example, if a company was worth $10M and there was a total of 1M shares owned by shareholders, then each share would be worth $10.

In a stock market, all companies and their stock are identified by symbols, which are short character strings. For example, Amazon's symbol is AMZN, Apple's is AAPL, and Microsoft's is MSFT.
An investor will buy some number of shares at a specific purchase price and pay a small fee to abroker to complete that transaction. Then, at late time, the investor will sell all or some of those shares at a sales price and pay another small fee to a broker. Obviously, if an investor sells at a price higher than the purchase price (adjusting for the fees), the investor will make money. For example, if an investor buy 10 shares of AMZN at $800/share for a $10 fee, then sell those 10 shares at $850/share for $10 fee, that investor will make a profit of $480 (850*10 - 10 - 800*10 - 10).

For taxes purpose and asset management, investors correlate the sale of a block of stocks to specific purchases. For example,
